Function	R	Python
Add a column	<p><b><i>student_score['cust_keys'] = custom_keys</i></b> - #in a dataframe</p> <pre> {r} #Adding a column in a dataframe custom_keys = 1000:1394 student_score['cust_keys'] = custom_keys student_score %&gt;% head() </pre>  <p>6 rows   26-35 of 34 columns</p>	<p><b><i>student_score['cust_keys'] = custom_keys</i></b></p> <pre> #Add index values as a series in the data frame custom_keys = list(range(1000,1395)) student_score['cust_keys']=custom_keys </pre> <pre>student_score.head()</pre>  <p>5 rows x 34 columns</p>
Custom row index	<p>Custom indices can be set only for data tables, not data frames. In a data table, only secondary indices can be set.</p> <p><b><i>setindex(student_score_dt,cust_keys)</i></b></p> <pre> {r} #Custom Index setindex(student_score_dt,cust_keys) indices(student_score_dt) </pre> <pre>[1] "cust_keys"</pre>	<p>Add the custom index values as a series in the dataframe, if not already present. The column 'cust_keys' will act as secondary index. The original row index remains as-is.</p> <p><b><i>student_score.set_index('cust_keys')</i></b></p> <pre> #Custom Index student_score.set_index('cust_keys', inplace=True) student_score.loc[1000:1009] </pre>  <p>10 rows x 33 columns</p>

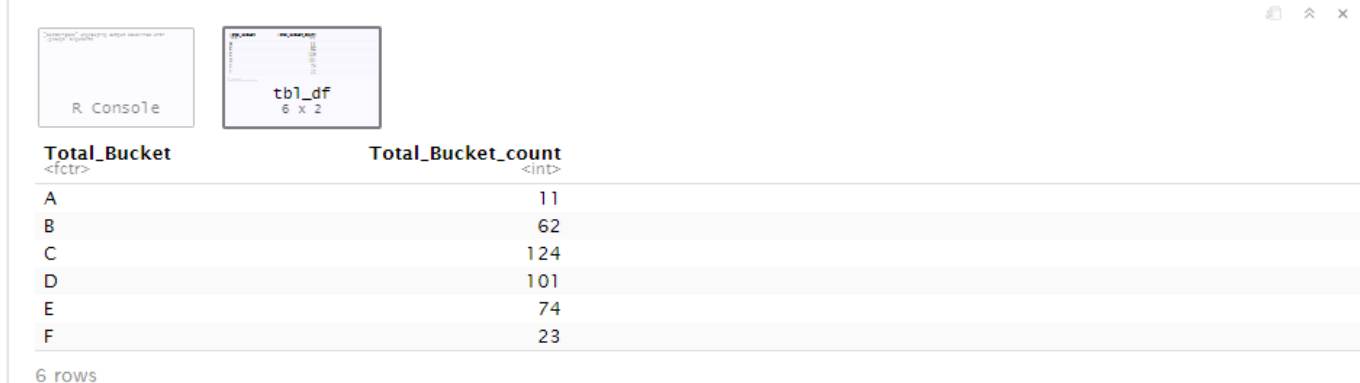

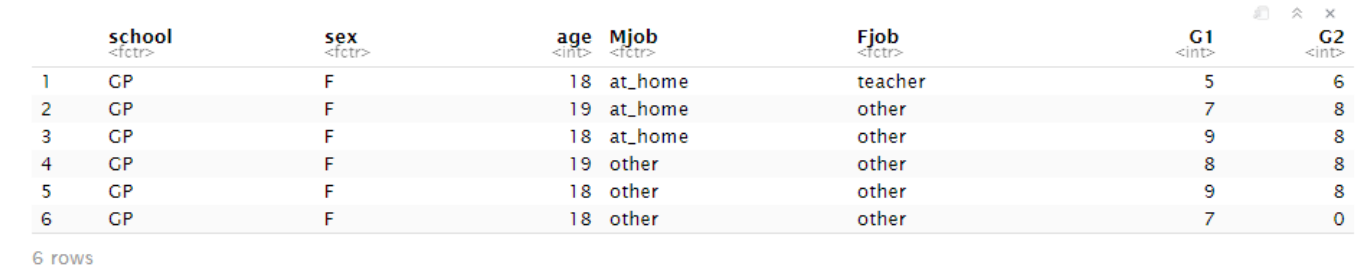

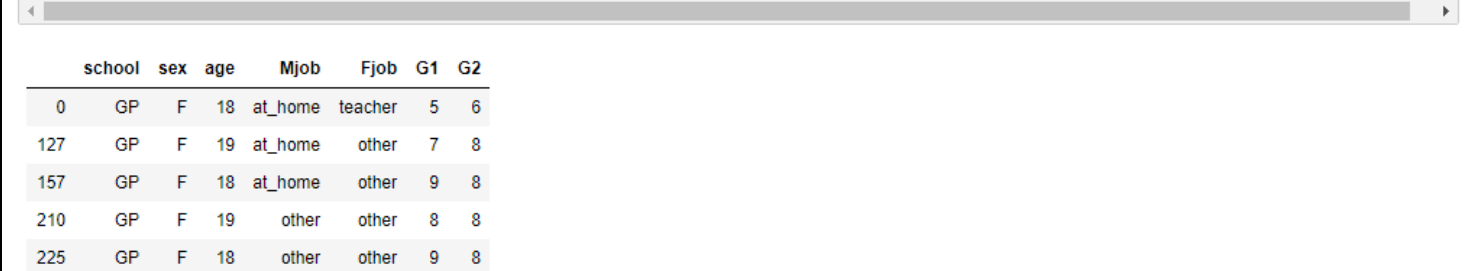

Function	R	Python
Access rows using custom index	<p><b><i>student_score_dt[(1002:1009)]</i></b></p> <pre> {r} #Custom Index setindex(student_score_dt,cust_keys) indices(student_score_dt) student_score_dt[(1002:1009)] </pre> 	<p><b><i>student_score.loc[1002:1009]</i></b></p> <pre> student_score.loc[1002:1009] </pre> 
Access rows with row indices	<p>Accessing the rows with the row indices is similar to the previous example above.</p> <p><b><i>student_score[3:10,]</i></b></p> <pre> {r} #Select custom rows student_score[3:10,] </pre> 	<p>When custom indices are introduced, accessing the row indices is done with the 'iloc' function.</p> <p><b><i>student_score.iloc[2:10]</i></b></p> <pre> student_score.iloc[2:10] </pre> 
Reset custom row index	<p>The secondary indices will be deleted.</p> <p><b><i>setindex(student_score_dt,NULL)</i></b></p> <pre> {r} #Remove secondary index setindex(student_score_dt,NULL) indices(student_score_dt) </pre> <p>NULL</p> 	<p>The secondary indices will be deleted.</p> <p><b><i>student_score.reset_index()</i></b></p> <pre> student_score.reset_index().head() </pre> 

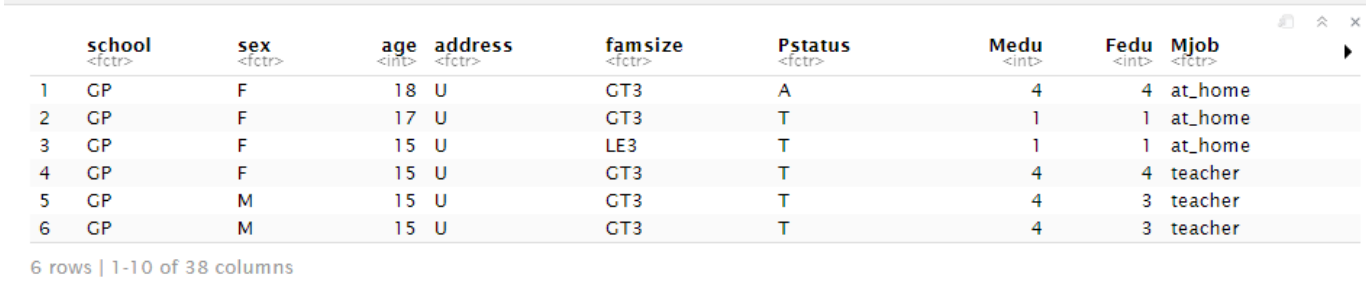

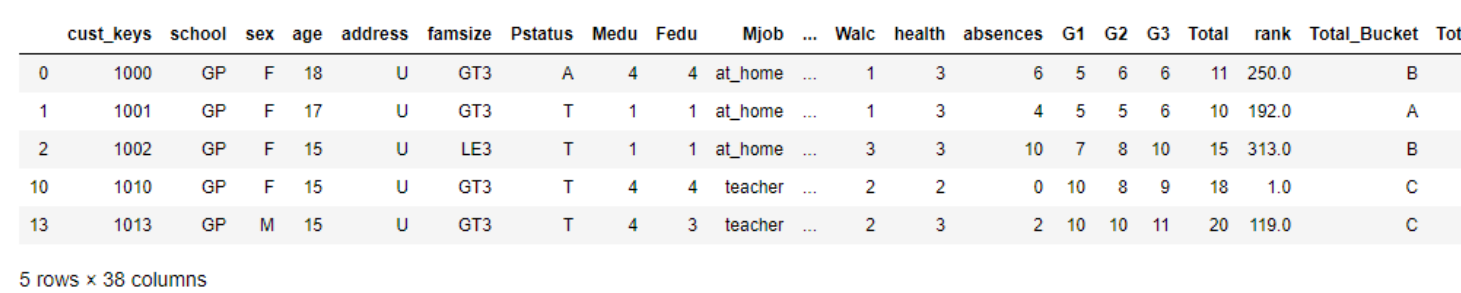

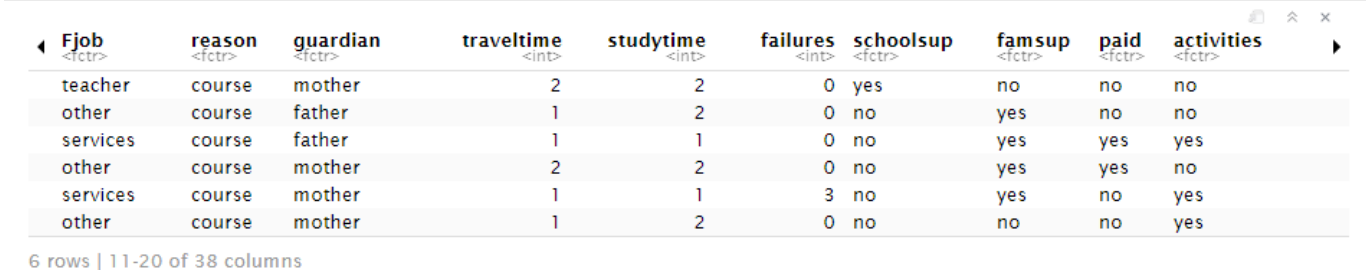

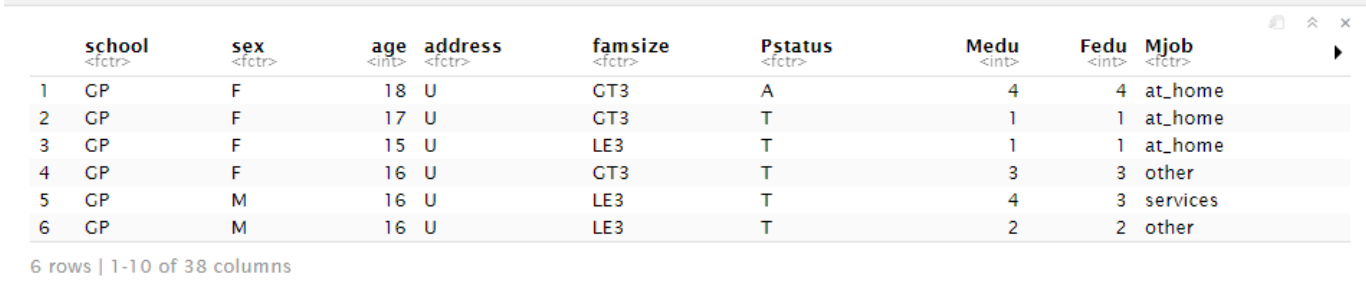

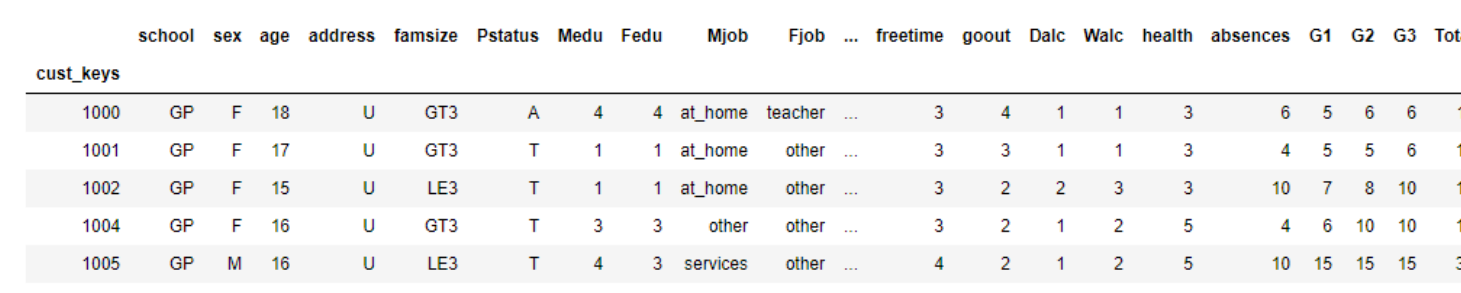

Function	R	Python
Add column with values computed from existing columns	<p><b><i>student_score[‘Total’]=student_score\$G1 + student_score\$G2</i></b></p> <pre> {r} #Adding a column with values computed from two columns in the existing dataset student_score[‘Total’]=student_score\$G1+student_score\$G2 student_score %&gt;% head() </pre>  <p>6 rows   27-36 of 35 columns</p>	<p><b><i>student_score[‘Total’] = student_score[‘G1’] + student_score[‘G2’]</i></b></p> <pre> student_score[‘Total’]=student_score[‘G1’]+student_score[‘G2’] student_score.head() </pre>  <p>rows × 34 columns</p>
Drop Column(s)	<p>All columns except the ones mentioned below will be selected.</p> <p><b><i>select(student_score, -c(Total,cust_keys))</i></b></p> <pre> {r} #Drop column(s) select(student_score, -c(Total,cust_keys)) %&gt;% head() </pre>  <p>6 rows   25-34 of 33 columns</p>	<p>The series specified in the function will be dropped. Axis = 1 represents the columns. By specifying axis = 0 and row indices (primary or secondary), the specific rows will be dropped.</p> <p><b><i>student_score.drop([‘Total’, ‘cust_keys’], axis=1)</i></b></p> <pre> student_score.drop([‘Total’, ‘cust_keys’], axis=1).head() </pre>  <p>5 rows × 33 columns</p>
Statistic of one column	<p>Other statistics like min, max, sum, etc. can be calculated the same way, as below.</p> <p><b><i>mean(student_score\$G1)</i></b></p> <pre> {r} #Statistic of one column mean(student_score\$G1) </pre> 	<p>Other statistics like min, max, sum, etc. can be calculated the same way, as below.</p> <p><b><i>student_score[‘G1’].mean()</i></b></p> <pre> student_score[‘G1’].mean() </pre> 
Finding null values	<p><b><i>is.na(student_score\$address)</i></b></p> <p>Without the sum (as in the image below), the is.na() returns binary values – True/False. Sum being zero indicates that there are no null values in the given column.</p> <pre> {r} #Sum of null values in a column sum(is.na(student_score\$address)) </pre> 	<p><b><i>student_score[‘address’].isna()</i></b></p> <p>Without the sum (as in the image below), the isna() returns binary values – True/False. Sum being zero indicates that there are no null values in the given column.</p> <pre> student_score[‘address’].isna().sum() </pre> 

Function	R	Python																																																																																																																																																																																																																
Drop / Omit null values	<p>This function drops out the rows that has missing/na/null values.</p> <p><b><i>na.omit(student_score)</i></b></p> <pre>```{r} #Omit null values na.omit(student_score) ```</pre>	<p>This function drops out the rows that has missing/na/null values.</p> <p><b><i>student_score.dropna()</i></b></p> <pre>#Drop null values student_score.dropna()</pre>																																																																																																																																																																																																																
No. of unique values in a column	<p><b><i>nlevels(student_score\$Mjob)</i></b> - #No. of unique values <b><i>levels(student_score\$Mjob)</i></b> - #Returns unique values</p> <pre>```{r} #Unique values in a column nlevels(student_score\$Mjob) # No. of unique values levels(student_score\$Mjob)  # Returns unique values ```</pre> <pre>[1] 5 [1] "at_home" "health" "other" "services" "teacher"</pre>	<p><b><i>student_score['Mjob'].nunique()</i></b> - #No. of unique values <b><i>student_score['Mjob'].unique()</i></b> - #Returns unique values</p> <pre>#Unique values in a series student_score['Mjob'].nunique() #No. of unique values student_score['Mjob'].unique() #Returns unique values</pre> <pre>5  array(['at_home', 'health', 'other', 'services', 'teacher'], dtype=object)</pre>																																																																																																																																																																																																																
Count of unique values in a column	<p><b><i>student_score %&gt;% group_by %&gt;% summarise(MJob_count = n()) %&gt;% arrange(-MJob_count)</i></b> The column has to be grouped for similar values and the count is calculated using n(). Without the arrange function, the output will be arranged in ascending order of Mjob (the column in discussion).</p> <pre>```{r} #Count of unique values student_score %&gt;% group_by(Mjob) %&gt;% summarise(MJob_count = n()) %&gt;% arrange(-MJob_count) ```</pre> <div><div>R Console</div><div>tbl_df 5 x 2</div><table><tr><th>Mjob</th><th>MJob_count</th></tr><tr><td>other</td><td>141</td></tr><tr><td>services</td><td>103</td></tr><tr><td>at_home</td><td>59</td></tr><tr><td>teacher</td><td>58</td></tr><tr><td>health</td><td>34</td></tr></table><div>5 rows</div></div>	Mjob	MJob_count	other	141	services	103	at_home	59	teacher	58	health	34	<p>The output is automatically arranged in descending order of the values.</p> <p><b><i>student_score['Mjob'].value_counts()</i></b></p> <pre>#Count of unique values in a series student_score['Mjob'].value_counts()</pre> <pre>other      141 services   103 at_home     59 teacher     58 health      34 Name: Mjob, dtype: int64</pre>																																																																																																																																																																																																				
Mjob	MJob_count																																																																																																																																																																																																																	
other	141																																																																																																																																																																																																																	
services	103																																																																																																																																																																																																																	
at_home	59																																																																																																																																																																																																																	
teacher	58

Function	R	Python																																																																																																								
Convert numerical column into categorical buckets	<p>The cut function automatically divides the numerical column into 6 (breaks = 6 or as mentioned inside the function) buckets, depending on the values of the numerical column. The count of values in each bucket is found using the group_by and summarise functions.</p> <p>The number of breaks can be an integer, asking R to divide the values automatically (as below). Or, we can specify the intervals. For eg., the intervals can be taken as “0-10”, “10-15”, “15-20”..and so on (right exclusive). And hence, the labels should be one less than the number of bins given.</p> <p><b><i>student_score[“Total_Bucket”] = cut(student_score\$Total, 6 ,labels=c(“A”, “B”, “C”, “D”, “E”, “F”))</i></b></p> <pre>##{r} #Numerical column into automatic categorical buckets student_score[Total_Bucket]=cut(student_score\$Total,6,labels=c("A","B","C","D","E","F")) student_score %&gt;% group_by(Total_Bucket) %&gt;% summarise(Total_Bucket_count=n())</pre>  <table><thead><tr><th>Total_Bucket</th><th>Total_Bucket_count</th></tr></thead><tbody><tr><td>A</td><td>11</td></tr><tr><td>B</td><td>62</td></tr><tr><td>C</td><td>124</td></tr><tr><td>D</td><td>101</td></tr><tr><td>E</td><td>74</td></tr><tr><td>F</td><td>23</td></tr></tbody></table> <p>6 rows</p>	Total_Bucket	Total_Bucket_count	A	11	B	62	C	124	D	101	E	74	F	23	<p>The cut function is very similar in R and Python. Only change is, instead of breaks, in Python, it’s called bins. The number of bins can be an integer, asking python to divide the values automatically. Or, we can specify the intervals (as below). Here, the intervals are taken as “0-10”, “10-15”, “15-20”..and so on (right exclusive). And hence, the labels should be one less than the number of bins given.</p> <p><b><i>student_score[“Total_Bucket_custom”] = pd.cut(student_score[“Total”],bins=[0,10,15,20,25,30,40],labels=[“A”, “B”, “C”, “D”, “E”, “F”])</i></b></p> <pre>#Numerical column into custom categorical buckets student_score[Total_Bucket_custom]=pd.cut(student_score[Total],bins=[0,10,15,20,25,30,40],labels=["A","B","C","D","E","F"]) student_score[Total_Bucket_custom].value_counts()</pre> <pre>C    111 D     91 E     77 B     59 F     43 A     14 Name: Total_Bucket_custom, dtype: int64</pre>
